

## Report assignment 1

<https://github.com/HJ-HHuber>

---

|  |  |
|--|--|
| <code>n = int(input('How many results would you like? '))</code>   | <code># Request input from user: How many results would you like?</code><br><code># n is defined as integer variable</code><br><code># n represents the amount of calculated values in the function fibonacci_f</code>   |
| <code>fibonacci = []</code>  | <code># create an array with the name fibonacci</code><br><code># '[]' corresponds to an empty array</code>  |
| <code># start of definition fibonacci_f</code><br><code>def fibonacci_f(n):</code><br><code>    a=0</code><br><code>    b=1</code>   | <code># define function fibonacci_f with the input variable (n)</code><br><code># set variable a to value 0</code><br><code># set variable b to value 1</code>   |
| <code>    # start of the if, elif, else condition, because of the "special" cases (n==0), (n==1)</code><br><code>    if n==0:</code><br><code>        fibonacci.append('null')</code><br><code>    elif n==1:</code><br><code>        fibonacci.append(a)</code><br><code>    else:</code><br><code>        fibonacci.append(a)</code><br><code>        fibonacci.append(b)</code> | <code># if zero values are requested by input (n==0)</code><br><code># add null to the fibonacci array, which represents an empty array</code><br><code># elif one value is requested by input (n==1)</code><br><code># add value of a to the fibonacci array</code><br><code># else all other cases where (n&gt;1)</code><br><code># add value of a to the fibonacci array</code><br><code># add value of b to the fibonacci array</code> |
| <code>    for i in range(n-2):</code><br><code>array</code><br><code>        c = a + b</code><br><code>        a = b</code><br><code>        b = c</code><br><code>        fibonacci.append(c)</code>  | <code># for loop of variable i in range of (n-2), because a and b are already in</code><br><code>array</code><br><code># set third variable c to a + b which gives the following value</code><br><code># set variable a to b</code><br><code># set variable b to c</code><br><code># add value of c to the fibonacci array</code><br><code># end of the if, elif, else condition</code>  |
| <code>fibonacci_f(n)</code>  | <code># end of definition fibonacci_f</code>   |

---

---

# start of if, elif condition to consider two special cases and else for the 'normal' case

```
if n==0:                                     # if zero values are requested by input (n==0)
    print('No index request possible!')      # output of: No index request possible!
# index request makes no sense in this case because the fibonacci array is empty, respectively contains the element null
print(fibonacci)                            #print fibonacci array which corresponds to null
elif n==1:                                  # elif one value is requested by input (n==1)
    print('set index = 1, otherwise: n<i')   # output of: set index = 1, otherwise: n<i
# index request makes no sense in this case because the fibonacci array has only one element, therefore this element is given without index request
print(fibonacci)                            #print fibonacci array which corresponds to the first value, which is 0
else:                                       # else all other cases where (n>1)
    i1 = int(input('First index:'))          #request the first index i1 from user and define as int
    i2= input(('Second index:'))            #request the second index i2 from user and define as int
```

---

# start of another if clause within the else to exclude a case where  $n < i1$  or  $n < i2$ . This means the user requests a higher index than elements are in the array.

```
if n<i1 or n<i2:                            # start if clause with  $n < i1$  or  $n < i2$ 
    print('Are you kidding me? !  $n < i$  ! ->ERROR') # output of: Are you kidding me? !  $n < i$  ! ->ERROR
else:                                       # start else for all cases where both indexes  $< n$ 
    print('value 1:', fibonacci[i1-1])     # output of: value 1: requested value with index i1-1 from fibonacci
    print('value 2:', fibonacci[i2-1])     # output of: value 2: requested value with index i1-1 from fibonacci
# end of if, else clause
```

---

# end of if, elif, else condition

---
